Finding Citizens in Poverty

Finding those in poverty

- We want to find citizens who are living in poverty.
- Women and girls living in poverty are at risk of modern-day slavery, Femal Genital Mutilation and high perinatal mortality rates.
- Currently, there are no reliable estimates of poverty rates in Dar es Salaam, Tanzania.

“It’s no longer a crime to publish statistics in Tanzania”

The Citizen, 29th June 2019

Citizens

Know the local area

Have up to date knowledge

Are enthusiastic

Are expensive to ask

May be biased

Need to be sampled

Comparative Judgement Methods

The Bradley-Terry Model

- Y_{ij} is the number of times i beats j
 - π_{ij} is the probability i beats j
 - λ_i is the quality of subward i
-
- All judgements are independent
 - All judges have the same perception of each subward

$$Y_{ij} \sim \text{Binomial}(n_{ij}, \pi_{ij})$$

$$\pi_{ij} = \frac{\lambda_i}{\lambda_i + \lambda_j}$$

$$\text{logit}(\pi_{ij}) = \lambda_i - \lambda_j$$

We assume the level of poverty in each subward depends on its location in the city, the suburb it's in, and its immediate neighbours.

$$\lambda_i = p_1 f_{city}(x_i, y_i) + p_2 f_{suburb}(x_i, y_i) + p_3 f_{neighbour}(x_i, y_i)$$

We model the functions non parametrically using Gaussian Processes.

$$f \sim \mathcal{GP}(0, \Sigma)$$

The parameters p_1 , p_2 , and p_3 describe how important each function is.

We allow for each judge to have a different perception on each subward.

$$\lambda_{ig} \sim N(\lambda_i, \sigma_g^2)$$

The noise parameter for judge g , σ_g^2 , tells us how reliable judge g is.

This increases the number of parameters in the model:

- 173 reliability parameters
- $173 * 452 = 78,196$ perceived quality parameters.

function

Quantifying Uncertainty in the Results

Proportion of judges who knew each subward

Uncertainty in results

The judge reliability results are still a work in progress. So far we have found:

- The vast majority of judges agree on the vulnerability in each subward.
- We need to do a better job at finding citizens from all over the city.
- First thing in the morning and after lunch are the best times to collect data.
